BAFU integration
Progress for review

13 November 2026 | Premise development branch: premise-CLIC

Seven of 19 sectors have passed a real scenario build and export. The example notebook remains a simple three-sector workflow: biomass, electricity and heat. The full integration is still in progress.

Checked sector	What the review can inspect
Biomass	Regional supply mixes and connected native consumers
Electricity	IAM regional markets, including EUR and NEU; voltage chains
Heat	Regional supply and delivery, efficiencies and consumer links
Cement	Regional clinker and native cement grades
Steel	Distinct native grades and processing inventories
Mining	Regional tailings markets and linked disposal consumers
Renewables	119 wind variants retaining their source inventories

What has actually been checked

The seven-sector REMIND SSP2-NPi 2050 export contains 14,902 activities and retains all 11,947 native source activities. Checks cover complete supplier links, expected regional outputs and finite life-cycle inventories. These results apply to BAFU 2026 with the ecoinvent 3.10 biosphere and this scenario; they are not a guarantee for every IAM scenario or impact score.

Recent work

Carbon-removal preparation exposed missing reviews for equipment and waste-treatment mappings. The pump and solvent-treatment reviews are extended. An incorrect shared-cogeneration-component match is corrected to the heat exchanger supported by the source inventory. Chiller and turbine reviews now cover directly inspected source versions. Waste-treatment signs, signed credits, formulas and uncertainty are preserved.

Important limits

Carbon removal is not yet qualified. Its next stop is another ecoinvent 3.12 correspondence. The other unfinished sectors are fuels, metals, batteries, transport, final energy and emissions. Proxies and omissions remain visible warnings. The prepared source bundle also excludes 2,991 unsupported biosphere exchanges. Finite inventories do not prove complete or equivalent impact scores.

Test the notebook and inspect the result

The normal user workflow stays unchanged. No separate UVEK sector engine.

1. Get the branch and install it

Fork **polca/premise** on GitHub, clone your fork, fetch the upstream **premise-CLIC** branch and switch to it. The colleague guide gives the exact Git commands. In that checkout, create an environment and register its kernel:

```
conda create -n premise-review python=3.12 pip -y
conda activate premise-review
python -m pip install -e ".[bw25]" jupyterlab ipykernel nbformat
python -m ipykernel install --user --name premise
jupyter lab examples/uvek_2026_review_workflow.ipynb
```

2. Prepare the local data

Use your regular Brightway directory. The notebook expects project **bafu-2026-ecospold2-biosphere-310**, source database **BAFU:2026-reimported** and biosphere **ecoinvent-3.10-biosphere**. Obtain the prepared source bundle and IAM key from Romain. They are not included in Git. The source database is read, not overwritten.

3. Run and explore

Select the **premise** kernel and run the cells in order. Enter the IAM key at the password prompt. The notebook exports a new timestamped database, lists regional electricity markets, shows EUR and NEU suppliers, searches heat activities and solves an electricity inventory. Save the export name and both software revisions with your feedback.

Latest notebook check: all nine code cells ran in order on 13 November, producing 13,626 activities. Export counts can change as the CLIC archive evolves.

Expect 39 base regional electricity markets, plus additional period-average markets. Original country datasets can remain as handovers to regional markets. Inspect their exchanges before interpreting them as duplicate supply. Review loss assumptions, geographic substitutions and mapping warnings. The example calculates an inventory, not an impact score.

What remains, and how we will work

Keep testing the seven qualified sectors while finishing the other 12. Next: clear the remaining carbon-removal dependencies, then test its shared update, filters, supplier links and export. Other sectors need the same evidence, or a documented reason that the scenario has no applicable IAM data. A cleared mapping alone does not make a sector operational.

Work primarily changes Premise mappings and Brightpath migration resources. Runtime Python changes need a reproduced problem that mappings cannot solve. Decisions and limitations are logged for review. Keep focused commits and push batches of roughly 5-10; local commits can therefore be ahead of GitHub. There is no reliable completion date yet.
